Predicting the severity of motor vehicle collisions

1 Introduction

This project aims to develop a model that can be used to predict the expected severity of a motor vehicle accidents (should one occur) based on road conditions, weather and other environmental attributes derived from real world motor vehicle accident statistics. The model could be of interest to the following stakeholders

- Satellite Navigation providers who could combine this severity (consequence)
 model with model for computing accident likelihood based on locations, thus
 allowing the provider to deliver a navigation along the lowest risk route
- Emergency service dispatchers who could use the model for decision support or supplementary information when determining a course of action to take when calls are received with insufficient details about a motor vehicle collision

2 DATA

At a minimum, the following data is required to construct a model to estimate accident severity

- Collision statistics that include a severity measure
- Location information or road characteristics for each of the collisions to allow extrapolation to other similar sections of road
- Road surface condition and other environmental features that relate to each of the collisions

The viability of producing an accurate collision severity model will utilise the collision data from the Seattle Police Department accessible via the following link: <u>Seattle Collision Data</u>.

A description of the dataset can be found via the following link: Seattle Collision Metadata.

3 METHODOLOGY

3.1 EXPLORATORY DATA ANALYSIS

From the Metadata descriptions and inspecting the output of the head function, the following columns containing identifier and key values will not be investigated:

- OBJECTID
- INCKEY
- COLDETKEY
- REPORTNO

The remaining columns were examined through some high-level statistical analysis of the data to aid in narrowing down relevant features.

The following figures contain the result of applying the 'describe' method to the columns of the data.

3.1.1 Geospatial View

NaN

75%

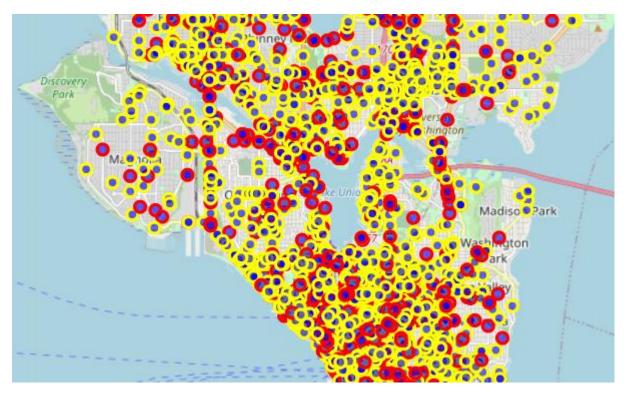

A plot of Seattle with an overview of property damage (yellow) and injury (red) for the first five thousand data points was produced to see if location was significant in the outcome of an incident.

1.015501e+07

0.000000e+00

5.239700e+06

NaN 0.000000 NaN 525241.000000

The overview of the first five thousand collisions did not appear to show an obvious bias based on location so will not be used in modelling.

3.1.2 Analysing Discrete Features

Several the columns contain discrete values which merit further investigation. The value_counts method is used to provide a quick overview of the data. An example of the output examined is:

After assessing all remaining columns, the following are candidates for further analysis:

- ADDRTYPE appears useful for generic prediction along routes as Block, Intersection and Alley are relatively easy to determine for other road networks
- JUNCTIONTYPE may be used if there is correlation with severity
- WEATHER, ROADCOND and LIGHTCOND are likely to be useful and will require further analysis

The following columns may be useful during data cleansing and subsequently improving the model:

- EXCEPTRSNCODE and EXCEPTRSNDECS may be a useful detail to identify and drop incomplete information
- INCDATE may be evaluated further to determine whether season or month can improve the accuracy of the model beyond just weather, road condition or light
- INCDTTM may be used in place of INCDATE if date-based improvements are required

The remaining columns will not be investigated further:

- LOCATION appears too specific for a general-purpose prediction.
- SEVERITYCODE.1 and SEVERITYDESC appear to be duplicates of the SEVERITY column and will not be evaluated further
- COLLISIONTYPE is unlikely to be useful as a prediction of the collision type may be
 difficult to predict but it may be analysed further during modelling as it may be correlated
 with other features useful for determining routes (e.g. Left Turn at an intersection may be
 more likely to result in an injury which may require an alternate route)
- The counts will not be further evaluated as they are a consequence of a collision and are unlikely to predict severity
- INATTENTIONIND and UNDERINFL will not be used for predicting severity as they will not be an input into route planning
- All other columns will be excluded

3.1.3 Further Analysis

The candidate data columns require further analysis before inclusion in the model.

Firstly, the relationship between SEVERITYCODE and each of the candidates as well as some basic statistics (count, average and standard deviation). The mean and standard deviation are relevant as severity code is either 1 or 2, so a mean closer to 2 indicates more likelihood of an injury.

The figures below capture the results from each assessed column:

	SEVERITYCODE			
	count	mean	std	
ADDRTYPE				
Alley	751	1.109188	0.312082	
Block	126926	1.237115	0.425315	
Intersection	65070	1.427524	0.494723	

NOTE: ADDRTYPE will be used in the model as there is a significant severity ratio difference between Alley, Block and Intersection.

	SEVERITYCODE		
	count mean std		
JUNCTIONTYPE			
At Intersection (but not related to intersection)	2098	1.296949	0.457023
At Intersection (intersection related)	62810	1.432638	0.495446
Driveway Junction	10671	1.303064	0.459604
Mid-Block (but intersection related)	22790	1.320184	0.466557
Mid-Block (not related to intersection)	89800	1.216080	0.411572
Ramp Junction	166	1.325301	0.469905
Unknown	9	1.222222	0.440959

NOTE: JUNCTIONTYPE may be added to the model after the first iteration if accuracy needs to be improved because it looks like it overlaps with ADDRTYPE

SEVERITYCODE

	count	mean	std
WEATHER			
Blowing Sand/Dirt	56	1.267857	0.446850
Clear	111135	1.322491	0.467432

Other	235	1.221277	0.415992
Unknown	13473	1.044905	0.207102

NOTE: LIGHTCOND will be used in the model as there appears to be enough variation across the different light conditions that it may be useful.

3.2 DATA PREPARATION

Data preparation consisted of the following steps:

- Create a data-frame with the SEVERITYCODE, ADDRTYPE, WEATHER, ROADCOND and LIGHTCOND columns
- Drop all rows that have null entries in any of the columns it is assumed that there are sufficient data points that dropping data will have minimal impact on the model
- Replace all columns of discrete values with 'dummies' to represent each of the values.

The resultant data-frame has 33 columns and 187525 rows.

3.3 Model Development

The intent of the model is to classify collisions as either 'damage' or 'injury', hence classification machine learning models will be employed to predict injury. The selected models are Decision Trees, K-Nearest Neighbours (KNN), Support Vector Machines (SVM) and Logistic Regression. Note that Logistic Regression is applicable as there are only two labels in the dataset.

The prepared data-frame was split into Training and Test datasets consisting of 168772 and 18753 samples, respectively.

The test dataset contained 12920 damage and 5833 injury samples.

As the samples are biased, the baseline for the model performance should be an improvement on always selecting 'damage' which would yield accuracy of 68.9%.

As this is a classification problem, the following models were produced, analysed and summarised in the following table:

Model	Parameters	Test set accuracy
KNN	K = 4	66.3%
Decision Tree	criterion="entropy", max_depth = 6	68.9%
SVC	kernel='rbf'	68.9%
Logistic	C=0.01, solver='liblinear'	68.9%
Regression		

It should be noted that none of these models was an improvement on always selecting property damage.

After the initial modelling, attempts were made to use different encoding schemes for the discrete values as well as using the StandardScaler and neither improved the predictions.

The correlations were produced for the training dataset and inspecting these showed that the correlations between the SEVERITYCODE and each to the 32 columns confirmed that there is low correlation between any individual column and the occurrence of injury.

4 RESULTS

The result of the investigation is that although nearly 30% of collisions result in an injury, it is not feasible to predict whether or not a collision will result in an injury based on the type of road, weather, condition of road and light conditions.

5 Discussion

Given the poor correlation between any individual feature and injury, it is highly unlikely that an accurate model can be produced from the analysed data.

Although using the actual injury likelihood at a given location may result in a better prediction, it is not useful for a general route planning application.

Further investigation could be conducted into whether temporal information could play a significant role in predicting injury, such as time of day, day of week or season of year, but this is unlikely to be useful for route planning or service allocation as it is not location based.

6 Conclusion

Based on the data analysed and the classification models investigated, it was not possible to build a classification model that could outperform always predicting that an injury did not occur. Instead, other data or modelling techniques are required to build a reliable predictive model.
